Goals & Objectives: To understand the differential diagnosis & management of constipation in the pediatric patient:

- Name 8 diagnoses in the differential diagnosis of constipation.
- Identify at least 5 “red flags” in the history of a patient presenting with constipation.
- List the medications (oral and rectal) used in constipation and their indications.
- Write out the behavioral and dietary management of constipation.

Pre-Meeting Preparation:
Please read/review the following enclosures:

- “Evaluation & Treatment of Constipation in Infants & Children” (AAFP, 2006)
- Patient Resources: Parent Handout; Stool Diary; Management Plan

Conference Agenda:

- Review Constipation Quiz
- Complete Constipation Cases
- “Hands-on” Activity: Using a finger inserted into a balled fist, simulate the DRE findings of the following conditions: Hirschsprung’s, neurologic dysfunction, functional constipation, and normal anal tone.

Post-Conference: Board Review Q&A

Extra-Credit:

- Childhood Defecation Disorders (IFFGD, 2006)—parent-friendly review
- Prevalence, Symptoms, & Outcome of Constipation in Infants & Toddlers (JPeds, 2005)
- Evaluation & Treatment of Constipation: Recs from NASPGHN (CPG, 2006)
Evaluation and Treatment of Constipation in Infants and Children

WENDY S. BIGGS, M.D., and WILLIAM H. DERY, M.D.
Michigan State University College of Human Medicine, East Lansing, Michigan

Constipation in children usually is functional and the result of stool retention. However, family physicians must be alert for red flags that may indicate the presence of an uncommon but serious organic cause of constipation, such as Hirschsprung’s disease (congenital aganglionic megacolon), pseudo-obstruction, spinal cord abnormality, hypothyroidism, diabetes insipidus, cystic fibrosis, gluten enteropathy, or congenital anorectal malformation. Treatment of functional constipation involves disimpaction using oral or rectal medication. Polyethylene glycol is effective and well tolerated, but a number of alternatives are available. After disimpaction, a maintenance program may be required for months to years because relapse of functional constipation is common. Maintenance medications include mineral oil, lactulose, milk of magnesia, polyethylene glycol powder, and sorbitol. Education of the family and, when possible, the child is instrumental in improving functional constipation. Behavioral education improves response to treatment; biofeedback training does not. Because cow’s milk may promote constipation in some children, a trial of withholding milk may be considered. Adding fiber to the diet may improve constipation. Despite treatment, only 50 to 70 percent of children with functional constipation demonstrate long-term improvement. (Am Fam Physician 2006;73:469-77, 479-80, 481-2. Copyright © 2006 American Academy of Family Physicians.)

► Patient information: Two patient information handouts on constipation in children, written by the authors of this article, are provided on pages 479 and 481.

Constipation has been defined as “a delay or difficulty in defecation, present for two or more weeks, sufficient to cause significant distress to the patient.”1 This condition is responsible for an estimated 3 to 5 percent of physician visits by children.2 Constipation often causes more distress to parents and other caregivers than to the affected child. Many caregivers worry that a child’s constipation is the sign of a serious medical problem.

As children age, normal physiologic changes occur in the intestines and colon that decrease the daily number of stools from a mean of 2.2 in infants younger than one year to a mean of 1.4 in one- to three-year-old children (Table 1).1,3 Thus, less frequent stooling may not be constipation. If, however, constipation is defined as “failure to evacuate the lower colon completely,”4 even children who stool daily in small amounts may be considered to have constipation. Encopresis, which is the involuntary leakage of feces into the undergarments, may be an indication of constipation.

This article reviews the differentiation of organic and functional constipation in infants and children. The treatment of functional constipation also is reviewed.

Epidemiology

Up to one third of children ages six to 12 years report constipation during any given year.5 Constipation generally first appears between the ages of two and four years.6 Encopresis is reported by 35 percent of girls and 55 percent of boys who have constipation.7 In toddlers (ages two to four years), the distribution of constipation and soiling is equal in boys and girls. However, by school age (five years), encopresis is three times more common in boys than in girls.4 At the age of 10 years, approximately 1.6 percent of children still have some encopresis.4

Etiology and Pathophysiology

Continence is maintained by involuntary and voluntary muscle contractions. The internal anal sphincter has an involuntary resting tone that decreases when stool enters the rectum. The external anal sphincter is under voluntary control. The urge to defecate is triggered when stool comes into contact with the mucosa of the lower rectum.

If a child does not wish to defecate, he or she tightens the external anal sphincter and squeezes the gluteal muscles. These actions can push feces higher in the rectal vault and reduce the urge to defecate. If a
child frequently avoids defecating, the rectum eventually stretches to accommodate the retained fecal mass, and the propulsive power of the rectum is diminished.

The longer that feces remains in the rectum, the harder it becomes. Passage of a hard or large stool may cause a painful anal fissure. The cycle of avoiding bowel movements because of a fear of painful defecation may progress to stool retention and infrequent bowel movements, a condition that is termed functional constipation.

Most children who present with constipation have functional constipation. Rarely, however, constipation has a serious organic cause. For confident diagnosis of functional constipation, family physicians should be alert for warning signs that may indicate the presence of a pathologic condition (Table 2).5

Differential Diagnosis: Functional vs. Organic Constipation

NEONATES

Organic causes of constipation most commonly are found in neonates (Table 3).1 Failure to pass a meconium stool within 48 hours of birth should raise suspicion for Hirschsprung’s disease (congenital aganglionic megacolon). Hirschsprung’s disease occurs in one of 5,000 children and usually is diagnosed in infancy.1

In neonates, it is important to confirm the anatomic position and patency of the anus. The absence of an anal wink or a cremasteric reflex, the presence of a pilonidal dimple or hair tuft, or a decrease in lower extremity tone, strength, or reflexes may suggest a spinal cord abnormality such as tethered cord, myelomeningocele, or spinal cord tumor.

INFANTS

If Hirschsprung’s disease is not recognized in the neonatal period, the affected infant may present with symptoms such as abdominal distension, pencil-thin stools, failure to thrive, and bilious vomiting. If an infant has any of these symptoms, and the physical examination shows an empty rectum, Hirschsprung’s disease should be suspected. A delay in diagnosing this disease places the infant at risk for enterocolitis, with fever, explosive bloody diarrhea, and abdominal distension, in the second or third month of life.

Hypothyroidism is suggested in an infant with bradycardia, poor growth, and large fontanels. Cystic fibrosis may present with constipation and should be considered in an
infant with constipation and concomitant rash, failure to thrive, fever, or pneumonia.

CHILDREN

Functional constipation is the cause of symptoms of constipation in more than 95 percent of children older than one year. However, when warning signs are present, organic causes must be considered (Table 2).

Short-segment Hirschsprung’s disease may remain undiagnosed until a child is older than three years. Metabolic causes of constipation include hypercalcemia; hypothyroidism; and, more rarely, diabetes insipidus. Other causes include gluten enteropathy, cystic fibrosis, and lead toxicity.

Children with developmental or behavioral issues (e.g., mental retardation, autism, oppositional defiant disorder, depression) may be taking constipating medications such as opiates, phenobarbital, and tricyclic antidepressants.

Clinical Diagnosis

The findings of the history and physical examination are instrumental in differentiating functional from organic constipation in all children. Because the causes of constipation differ according to age, algorithms for the differential diagnosis are different for neonates and infants (Figure 1) and for children older than one year (Figure 2).

MEDICAL HISTORY

A careful history should be obtained to identify possible organic causes of constipation (Table 4). Functional constipation is almost always the diagnosis in children older than one year. The medical history generally confirms this diagnosis.

The passage of infrequent, large-caliber stools is highly suggestive of functional constipation. Fecal soiling, especially after a child has been toilet trained for some time, suggests rectal impaction from functional constipation. One study found that 78 percent of children with encopresis had fecal...

Return to A

Yes
Three or more stools per week and no soiling?

No
Wean from laxatives after six months.

Yes
Continue behavioral therapy and dietary changes; follow up at well-child visits.

Figure 2. Diagnosis and management of functional constipation and encopresis in children (age older than one year).

impaction. Approximately three of every four children with constipation have pain with defecation.\(^2\) The history may indicate that a child with constipation has a low-fiber diet containing few fruits and vegetables.

When evaluating children with constipation, family physicians should ask about toileting behavior, such as the timing of bowel movements, postures suggestive of stool retention (e.g., standing with legs crossed, rocking, squeezing the gluteal muscles), restricted access to toilets, and toilet avoidance or refusal.\(^1\)

**PhysiCal EXAMINatiOn**

A digital rectal examination should be performed to assess rectal tone and determine the presence of rectal distention or impaction (Table 4).\(^5\) The finding of rectal impaction may confirm the diagnosis of functional constipation. The presence of anal fissures (or papillae indicative of chronic anal fissures) also suggests functional constipation.

**DIAGNOSTIC TESTING**

If the rectal examination reveals fecal impaction, no confirmatory imaging studies are needed. If a rectal examination is not possible or is too traumatic for the child, abdominal radiography may be considered. One study\(^8\) found that a plain-film abdominal radiograph showing fecal impaction was highly predictive of the finding of fecal impaction on digital rectal examination. If stool is present in the rectum, a barium enema is no more useful than a plain-film radiograph. Computerized tomography is not indicated.

In the child with infrequent bowel movements and no signs of constipation, colonic transit time can be evaluated with radiopaque markers. When Hirschsprung’s disease is suspected, anal manometry is useful. Appropriate relaxation of the anal sphincter reliably excludes this disease.\(^1\)

**Treatment of Functional Constipation**

Early intervention may improve the chance for complete resolution of functional constipation.\(^7\) Treatment goals include disimpacting the rectum and then maintaining a regular bowel-movement routine. Months of treatment may be necessary before maintenance medications can be weaned.

**FAMILY EDUCatiOn**

Education for parents and caregivers is an important component of treatment for functional constipation. The affected child also should be educated if old enough to understand this medical problem and its treatment. By explaining the pathophysiology of functional constipation, family physicians can help parents and caregivers understand why the child is unable to have bowel movements of normal caliber and frequency. The child’s fear of a painful bowel movement is the most common motivating factor for fecal retention. The fecal retention seldom is an oppositional behavior. Furthermore, encopresis in a child usually is involuntary.

Dietary modifications commonly are recommended for children with functional constipation. One randomized controlled trial\(^9\) showed that fiber supplementation improved constipation better than placebo, especially in children with encopresis. A double-blind crossover study\(^10\) found that constipation may be a manifestation of cow's milk allergy in at least 1 out of 7 children with functional constipation.

milk intolerance in some children. Therefore, a trial of withholding milk for a brief period may be considered.

DISIMPACITION

Disimpaction can be accomplished with enemas, rectal suppositories, and oral agents (Table 5). No randomized controlled studies have compared methods of disimpaction. Rectal disimpaction with enemas is rapid, but it is also invasive and possibly traumatic for the child. A common protocol in children older than two years is to administer a mineral oil enema followed by a phosphate enema. Few studies have compared oral medications for disimpaction. In one study of children with chronic constipation,11 the osmotic laxative polyethylene glycol

(PEG 3350) was significantly more effective than lactulose during a two-week treatment period, and its use was preferred by 73 percent of caregivers. Randomized trials have found several different doses of polyethylene glycol to be effective for disimpacting children, with reasonable acceptance by parents and children. Other oral medications for rectal disimpaction include mineral oil, senna, polyethylene glycol electrolyte solution (GoLYTELY, NuLYTELY), and magnesium citrate.

**MAINTENANCE**

The goal is to maintain soft bowel movements once or twice a day. Ensuring regularity is important because rectal impaction can recur, restarting the constipation cycle.

Maintenance medications include mineral oil, lactulose, milk of magnesia, polyethylene glycol powder (MiraLax), and sorbitol. These and other maintenance medications vary in acceptance of use (Table 6).

Adjuncts to maintenance medications have been studied. In two randomized tri-
Information handouts that accompany this treatment plan is described in one of the patient information handouts that accompany this article.

A Cochrane review of data from eight studies found higher rates of persisting (up to 12 months) defecation problems when biofeedback training was added to conventional medical treatment. Therefore, biofeedback training is not recommended for children with functional constipation.

Long-Term Prognosis

Functional constipation is difficult to treat, and the relapse rate is high. In one study, 52 percent of children with constipation and encopresis still had symptoms after five years of treatment. A second study found that 30 percent of children who had been treated medically for constipation for a mean of 6.8 years continued to have intermittent constipation.

If a child’s symptoms do not improve after six months of good adherence to a treatment regimen, referral to a pediatric gastroenterologist may be warranted.

Constipation and Your Child

Bowel patterns vary from child to child just as they do in adults. What’s normal for your child may be different from what’s normal for another child. Most children have bowel movements 1 or 2 times a day. Other children may go 2 to 3 days or longer before passing a normal stool.

If your child doesn’t have daily bowel movements, you may worry that she is constipated. But if she is healthy and has normal stools without discomfort or pain, this may be her normal bowel pattern.

Children with constipation have stools that are hard, dry, and difficult or painful to pass. These stools may occur daily or may be less frequent. Although constipation can cause discomfort and pain, it’s usually temporary and can be treated.

Constipation is a common problem in children. It’s one of the main reasons children are referred to a specialist called a pediatric gastroenterologist. Read more to learn about constipation and its causes, symptoms, and treatments, as well as ways to prevent it.

What causes constipation?

Constipation frequently occurs for a variety of reasons.

- **Diet.** Changes in diet, or not enough fiber or fluid in your child’s diet, can cause constipation. (See “Getting enough fiber in your diet.”)
- **Illness.** If your child is sick and loses his appetite, a change in his diet can throw off his system and cause him to be constipated. Constipation may be a side effect of some medicines. Constipation may result from certain medical conditions (such as hypothyroidism or low thyroid).
- **Withholding.** Your child may withhold his stool for different reasons. He may withhold to avoid pain from passing a hard stool—it can be even more painful if your child has a bad diaper rash. Or he may be dealing with issues about independence and control—this is common between the ages of 2 and 5 years. Your child also may withhold because he simply doesn’t want to take a break from play. Your older child may withhold when he’s away from home, at camp or school, because he’s embarrassed or uncomfortable using a public toilet.
- **Other changes.** In general, any changes in your child’s routine (such as traveling, hot weather, or stressful situations) may affect his overall health and how his bowels function.

If constipation isn’t treated, it may get worse. The longer the stool stays inside the lower intestinal track, the larger, firmer, and drier it becomes. Then it becomes more difficult and painful to pass the stool. Your child may hold back his stool because of the pain. This creates a vicious cycle.

What are the symptoms of constipation?

Symptoms of constipation may include the following:

- Many days without normal bowel movements
- Hard stools that are difficult or painful to pass
- Abdominal pain (stomachaches, cramping, nausea)
- Rectal bleeding from tears called **fissures**

What is encopresis?

If your child withholds her stools, she may produce such large stools that her rectum stretches. She may no longer feel the urge to pass a stool until it is too big to be passed without the help of an enema, laxative, or other treatment. Sometimes only liquid can pass around the stool and leaks out onto your child’s underwear. The liquid stool may look like diarrhea, confusing both parent and pediatrician, but it’s not. This problem is called **encopresis.**

- Soiling (See “What is encopresis?”)
- Poor appetite
- Cranky behavior

You also may notice your child crossing her legs, making faces, stretching, clutching her buttocks, or twisting her body on the floor. It may look like your child is trying to push the stool out but instead she’s really trying to hold it in.

How is constipation treated?

Constipation is treated in different ways. Your pediatrician will recommend a treatment based on your child’s age and how serious the problem is. If your child’s case is severe, he may need a special medical test, such as an x-ray. In most cases, no tests are needed.

**Treatment of babies.** Constipation is rarely a problem in younger infants. It may become a problem when your baby starts solid foods. Your pediatrician may suggest adding more water or juice to your child’s diet.

**Treatment of older children.** When a child or teen is constipated, it may be because his diet doesn’t include enough high-fiber foods and water. Your pediatrician may suggest adding more high-fiber foods to your child’s diet, and encourage him to drink more water. These changes in your child’s diet will help get rid of abdominal pain from constipation.

**Severe cases.** If your child has a severe case of constipation, your pediatrician may prescribe medicine to soften or remove the stool. **Never give your child laxatives or enemas unless your pediatrician says it’s OK; laxatives can be dangerous to children if not used properly.** After the stool is removed, your pediatrician may suggest ways you can help your child develop good bowel habits to prevent stools from backing up again.

How can constipation be prevented?

Because each child’s bowel patterns are different, become familiar with your child’s normal bowel patterns. Make note of the usual size and consistency of her stools. This will help you and your pediatrician determine when constipation occurs and how severe the problem is. If your child doesn’t have normal bowel movements every few days, or is uncomfortable when stools are passed, she may need help in developing proper bowel habits.
Getting enough fiber in your diet
The American Academy of Pediatrics recommends that children between the ages of 2 and 19 years eat a daily amount of fiber that equals their age plus 5 grams of fiber. For example, 7 grams of fiber is recommended if your child is 2 years old (2 plus 5 grams).

The following are some high-fiber foods:

You can...
- Encourage your child to drink plenty of water and eat more high-fiber foods.
- Help your child set up a regular toilet routine.
- Encourage your child to be physically active. Exercise along with a balanced diet provides the foundation for a healthy, active life.

Remember
If you are concerned about your child’s bowel movements, talk with your pediatrician. A simple change in diet and exercise may be the answer. If not, your pediatrician can suggest a plan that works best for your child.

The information contained in this publication should not be used as a substitute for the medical care and advice of your pediatrician. There may be variations in treatment that your pediatrician may recommend based on individual facts and circumstances.

**Instructions:**
Write your child’s name and the time period in the upper right corner.
Write the day of the week and date in the first column.
When your child has a bowel movement in the toilet place an "X" in the appropriate column  
  (ie, during toilet sitting or outside of sitting time).
When your child sits on the toilet, but doesn’t have a bowel movement,  
  place an "O" in the appropriate column.
When your child takes his or her maintenance laxative, place a checkmark in the "Medication" column.
Write any additional information in the "Comments" column  
  (eg, need for rescue medication, episodes of wetting, soiling, or abdominal pain).
Keep this diary and bring it with you to the next appointment.
Constipation Management

I. Cleanout Phase
Give your child the following:

_____Miralax: Give ___ capful mixed in 8oz of liquid ___ times/day for ___days.
_____Pediatric Fleet Enema: Give _____enema ___times/day for ___days.
_____Dulcolax Tablets: Give ___ tablet ___times/day for ___ days.
_____Dulcolax Suppository: Insert 1 suppository into rectum ___ for ___days.
_____Magnesium Citrate: Drink ___oz ___times/day for ___days.
_____FleetsPhosphoSoda: Drink ____oz or ____cc ___times/day followed by 8 oz of water for ___days.

II. Maintenance Phase
After the cleanout phase is complete, give your child the following:

_____Miralax: Give ___ capful mixed in 8 oz of liquid ___times/day.
_____Milk of Magnesia: Give ___tablespoons ___teaspoons ___times/day.
_____Lactulose: Give ___tablespoons ___teaspoons ___times/day.
_____Mineral Oil: Give ___tablespoons ___teaspoons ___times/day.
_____Dulcolax Tablets: Give ___tablet ___times per week

III. Daily Behaviors
1. Make sure your child drinks plenty of water every day
2. Have your child sit on the toilet and try to have a bowel movement for 10 minutes each day approximately 30 minutes after breakfast and dinner. Give your child a foot stool to put his feet on if his feet do not touch the floor. Toilet time is not a punishment and should be a calm pleasant relaxed event. This is a very important part of your child’s care!
3. Increase your child’s intake of fresh fruits and vegetables.
4. Turn off the TV & computer, and have your child participate in some form of exercise for at least 30 minutes a day.

Constipation takes a long time to develop—and can take many months to correct. Please be patient with your child!

WRNMMC Pediatric Gastroenterology
**Constipation Quiz**

1. **Define Constipation:**
   A) Failure to evacuate the lower colon completely.
   B) A delay or difficulty in defecation for ≥2 weeks
   C) Type 1 & 2 on the [Bristol Stool Chart](#)
   D) <2 stools/wk & h/o of large diameter stools
   E) All of the Above

2. Please complete the following **laxative classification table:**

3. What is the goal of **maintenance therapy**? How long should it be continued?
Case 1:
Nicholas is a 6 year old male who presents with fecal soiling on a daily basis, which began in late October. He claims he "can't tell when" he is about to soil. His parents report multiple bouts daily of fecal urgency where he rushes to the toilet, only to pass small amounts of diarrheal stool. His toilet sitting behavior is peculiar in that he sits far back on the toilet seat with his knees extended and his toes pointed, straining at defecation. Once or twice weekly he will pass a very large caliber formed stool, which has on occasion plugged the plumbing. This pattern was not thought to be a problem by his parents as it began shortly after they began potty training him at two years old so that he could enter preschool earlier than rest of the neighborhood children.

What additional history would you like to know?

The dietary history finds that he eats the school breakfast and lunch, and will often not touch his vegetables at supper. Closer questioning indicates he does not pick fruit or vegetables from the salad bar at school, and the school typically offers only sweet buns or a burrito for breakfast. Physical examination finds a midline mass in the lower abdomen, with a rectal examination that shows a normally placed anus with an intact anal wink and a perineum coated with stool. The anus is shortened with the internal anal sphincter dilated by a massive amount of formed stool. You are unable to accurately assess the diameter of the rectum as the stool appears to fill the pelvic bowl. The stool tests negative for occult blood.

What diagnosis does this history/physical suggest?

What is the pathogenesis of this diagnosis? Draw a picture.
What are the key features of behavioral management for this patient?

How would you disimpact this patient?

What maintenance therapy would you provide?

What dietary recommendations would you make for this patient and family?

Case 2:  Mom calls you about Dina. She is a one month old female and mom is concerned because she hasn’t stooled in 3 days. Previously, she had stooled four to five times a day. She was a term delivery with no issues and stooled within the first 48 hours of life.

What other history questions would be important at this time?

Dina is exclusively breastfed, she is urinating well, continues to eat well and seems happy and playful. Her weight was over birthweight at her 2 week well child and there were no concerns during that visit. Her abdomen seems a little fuller to mom, but Dina does not seem bothered.

Are you concerned?

What is your advice for this mom? Should she be seen immediately? Tomorrow?
Dina is now 5 months old. Mom brings her in for a visit because every time she tries to start solid foods, Dina goes from stooling every 3-4 days (which has been her norm) to “never”. Mom reports the first time she tried solids (about 3 weeks ago) Dina went 7 days without stooling and was very uncomfortable and fussy. Mom finally gave her a glycerin suppository and stopped the solids for a little bit. A week or so later, she tried again with similar results. This time she had gotten some advice to try some clear juice, so she tried pear juice for 2 days with no success. Again, she had to give a suppository on the 7th day which produced a fairly explosive stool. She is growing well and is otherwise developmentally normal.

Are you concerned? Is there other history you would like to obtain?

What would be important on exam? What findings might increase your concern?
1. A 16-year-old girl presents with a complaint of constipation. She passes two to three small, pellet-like stools per week and claims that she has not experienced a "normal bowel movement" in 2 months. She usually skips breakfast and buys lunch at school. Both parents are employed, but the family tries to eat dinner together, usually at 8 pm during the week. Physical examination demonstrates a well-developed, well-nourished adolescent who has no unusual findings. Rectal examination reveals normal anal sphincter tone and an empty rectal vault.

**Of the following, the MOST appropriate treatment of this patient’s constipation includes**

A. lactulose  
B. methylcellulose  
C. milk of magnesia  
D. mineral oil  
E. polyethylene glycol

2. You are evaluating a 2-day-old term infant because of abdominal distention. He fed normally the first day after birth, but has had progressively increasing vomiting, which now is bilious. Physical examination demonstrates upslanted palpebral fissures, a prominent tongue, and mild hypotonia. Upon passage of a nasogastric tube, you aspirate 80 mL of green-yellow material from his stomach. Abdominal radiographs, including a left lateral decubitus film, reveal dilated loops of bowel and air-fluid levels but no evidence of pneumatosis.

**Of the following, the condition that BEST explains this baby’s clinical findings is**

A. duodenal atresia  
B. Hirschsprung disease  
C. meconium ileus  
D. necrotizing enterocolitis  
E. neonatal intussusception

3. A 5-year-old child presents to your office with a history of recurrent rectal prolapse that occurs at the time of bowel movements. Both the mother and child are very concerned when the rectal tissue protrudes from the anus, but the prolapse typically resolves without treatment.

**Of the following, the MOST common cause of rectal prolapse in children is**

A. celiac disease  
B. cystic fibrosis  
C. *Enterobius vermicularis* infestation (pinworms)  
D. functional constipation  
E. rectal polyps

4. A 3-year-old child presents with a history of intermittent painless rectal bleeding. Approximately once or twice a week, she passes a formed stool that contains up to “a teaspoon” of blood. Physical examination demonstrates no fissures or hemorrhoids. Hematocrit measurement and results of coagulation studies are normal. The bleeding persists despite stool softeners.

**Of the following, the test that is MOST likely to establish a diagnosis is**

A. colonoscopy  
B. computed tomography scan of the abdomen  
C. Meckel scan (radionuclide technetium scan)  
D. magnetic resonance angiography  
E. stool culture
